**Workshop on integrated modelling of nitrogen
28-30 November 2007, Laxenburg**

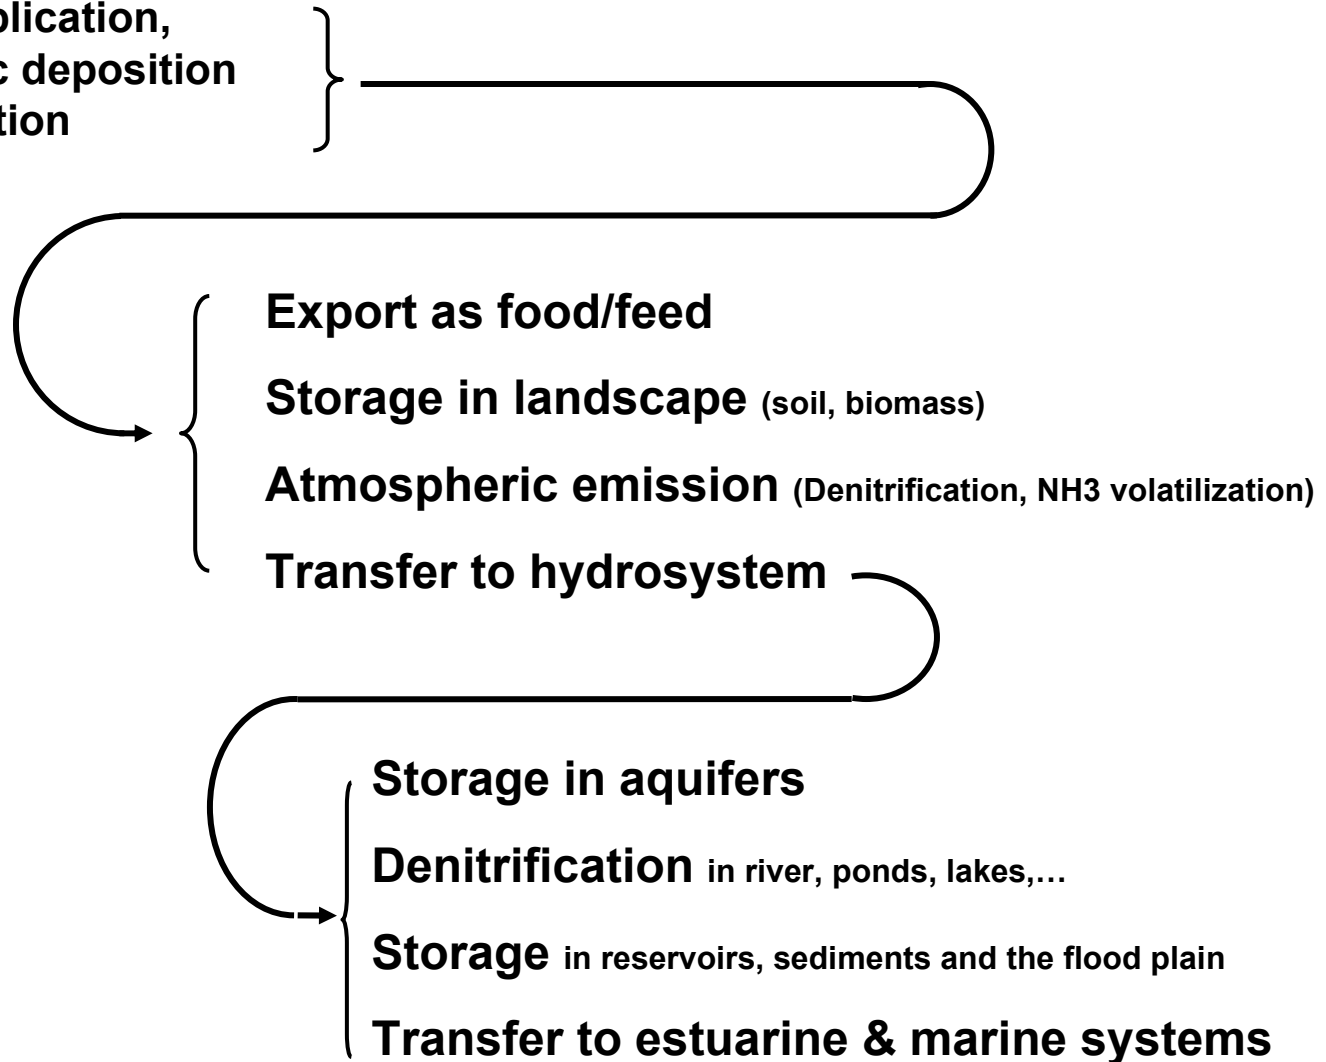

Modelling the N cascade at the regional scale

The question asked ?

Anthropogenic Inputs of reactive N:

fertilizer application,
atmospheric deposition
crop N₂ fixation

Different scales:

Plot Landscape **regional territory** **continent** whole globe

The scale of management decision and policy assessment

Regional watershed (5 000 - 100 000 km²)

**Regional territory
structured by a
drainage network**

Different approaches:

Black-box input-output budgets
→ regression models

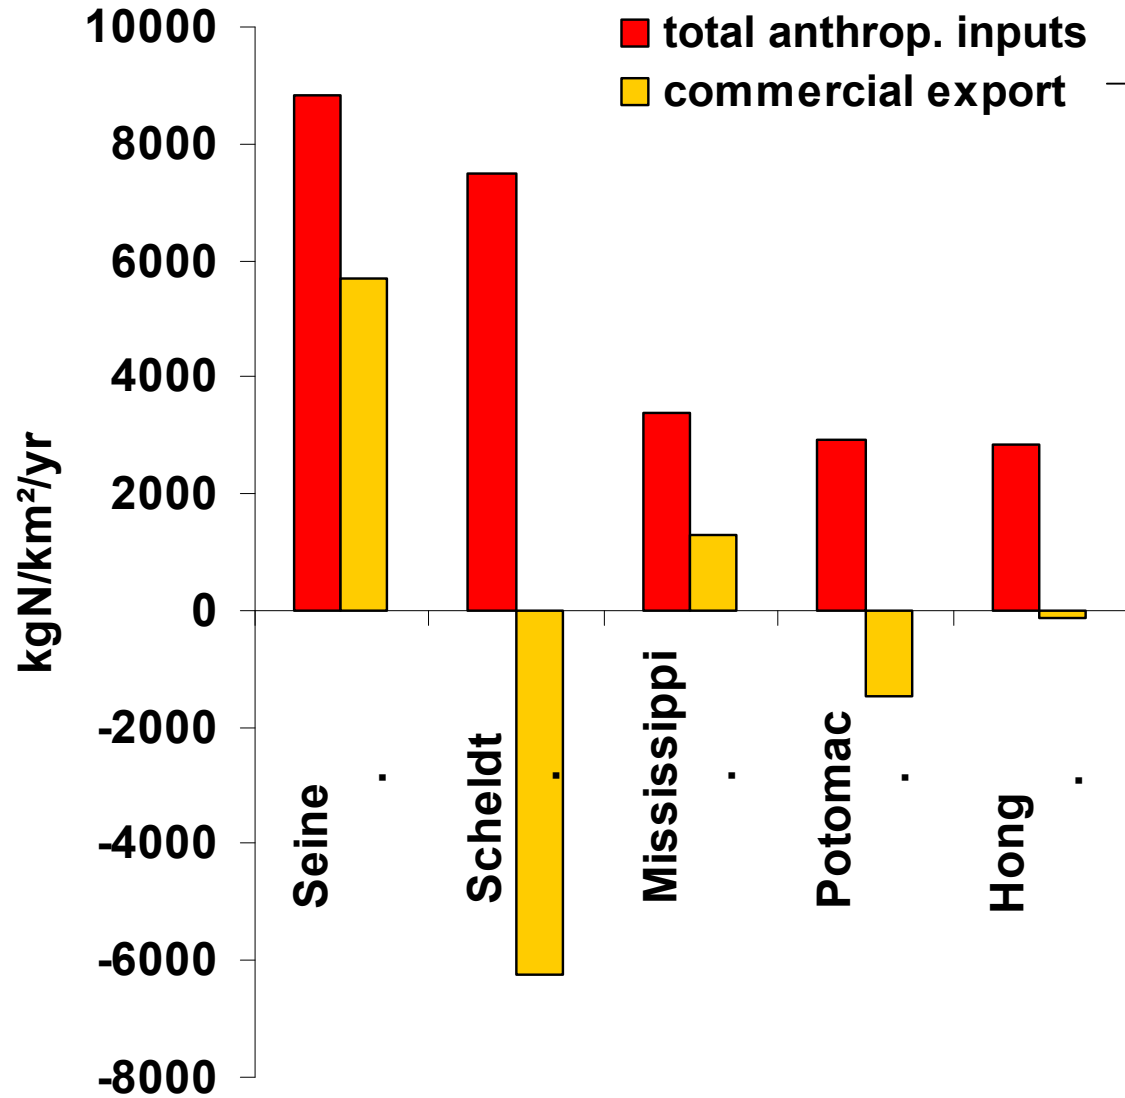

**Process-based, spatially distributed
models** of N dynamics within regional
systems.

input-output budgets

	<u>km²</u>	<u>inhab/km²</u>
Seine	65 000	190
Scheldt	19 900	520
Mississippi	3 230 000	20
Potomac	29 900	63
Hong (Vietnam)	156 500	200

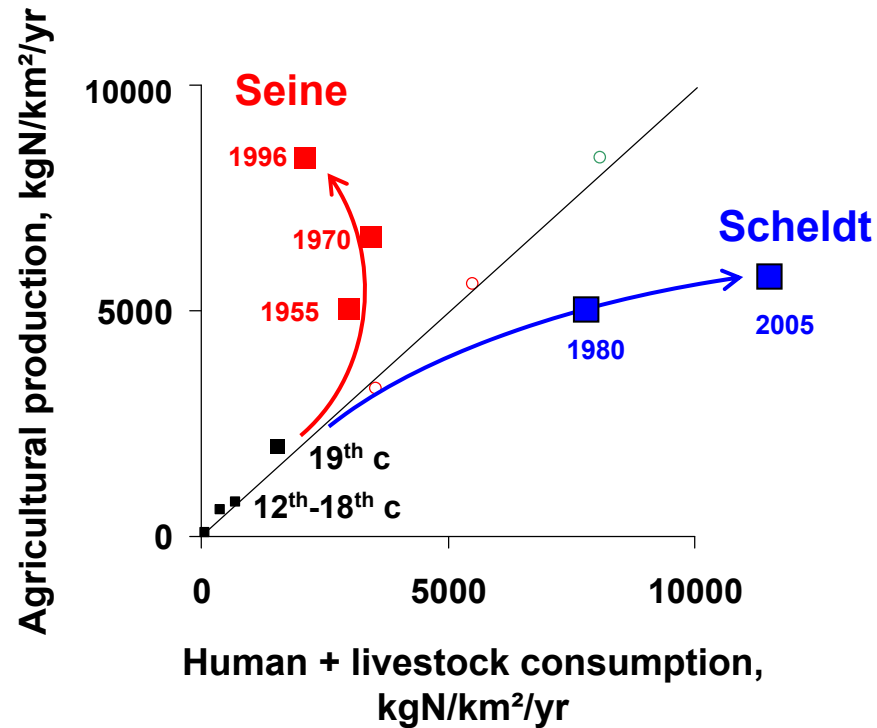

Export-Import balance of agricultural products across regional watershed limits

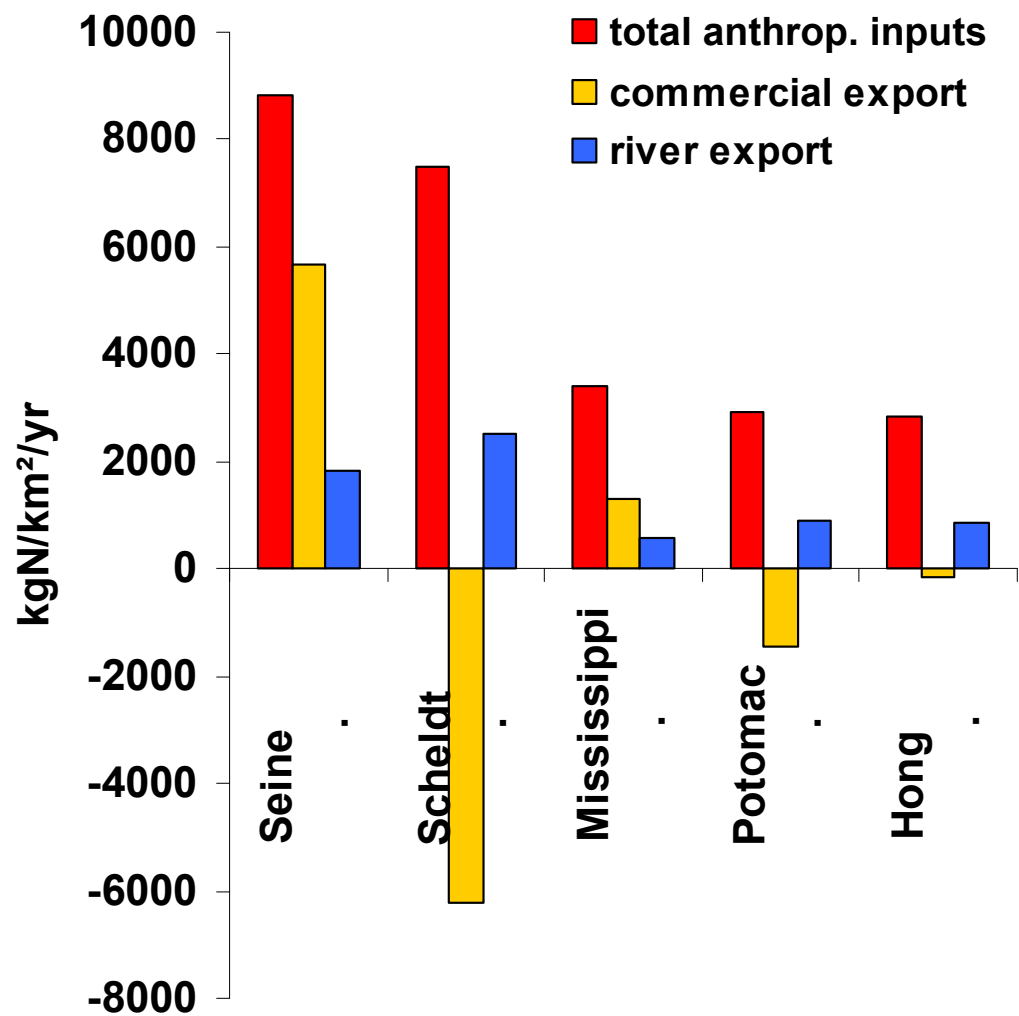

→ The balance between crop production (autotrophy) and consumption by human and livestock (heterotrophy)

The specialization of watersheds towards either autotrophy or heterotrophy is increasing since the last 50 years.

Riverine exports (N delivery to coastal marine systems)

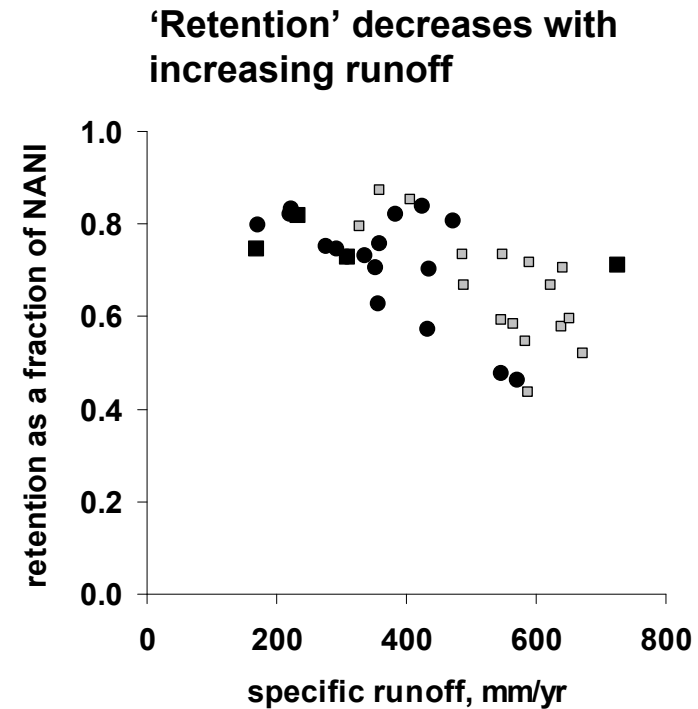

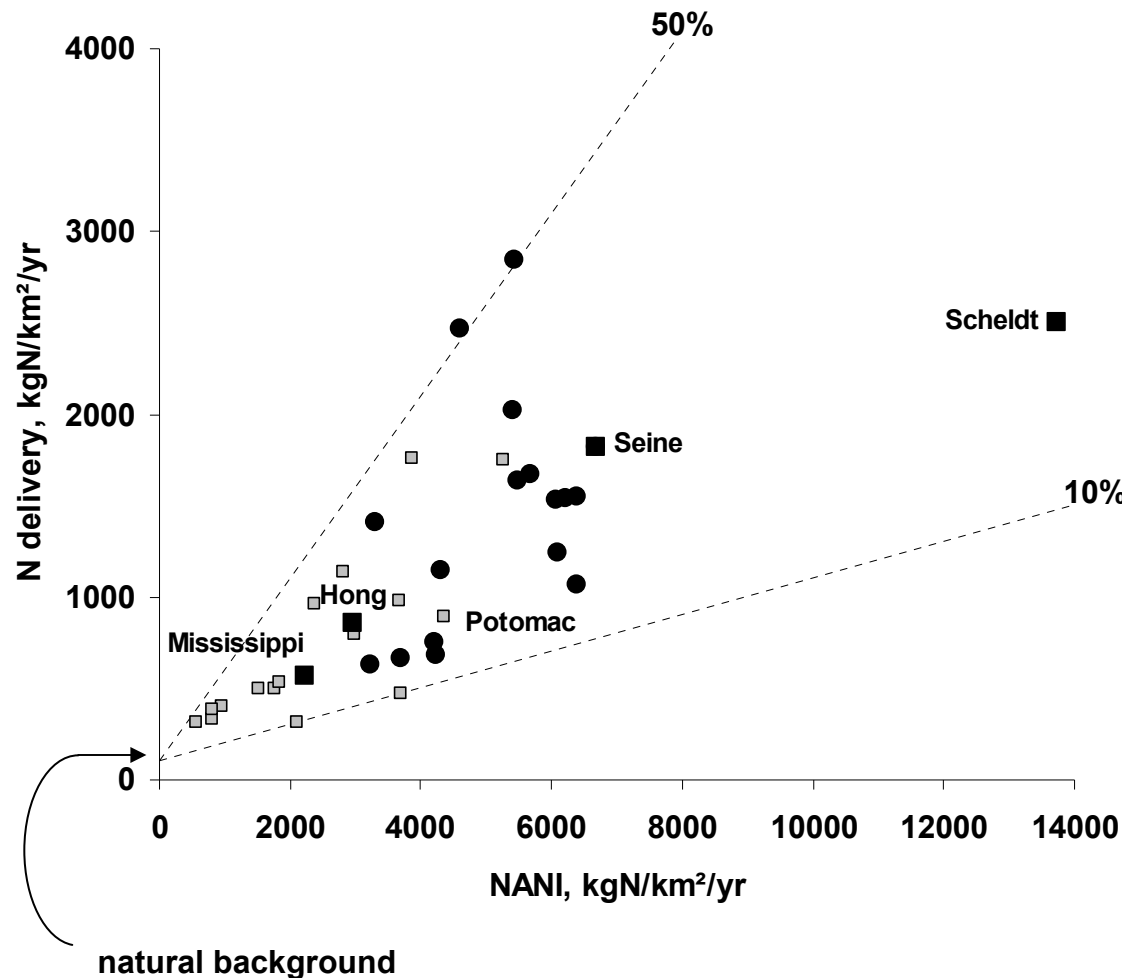

The 'NANI' models (Howarth et al., 1996; Boyer et al., 2002)

NANI (Net Anthropogenic N Inputs) = synth.Fertilizers + atm depos. + crop N₂ fix. + **net food/feed imports**

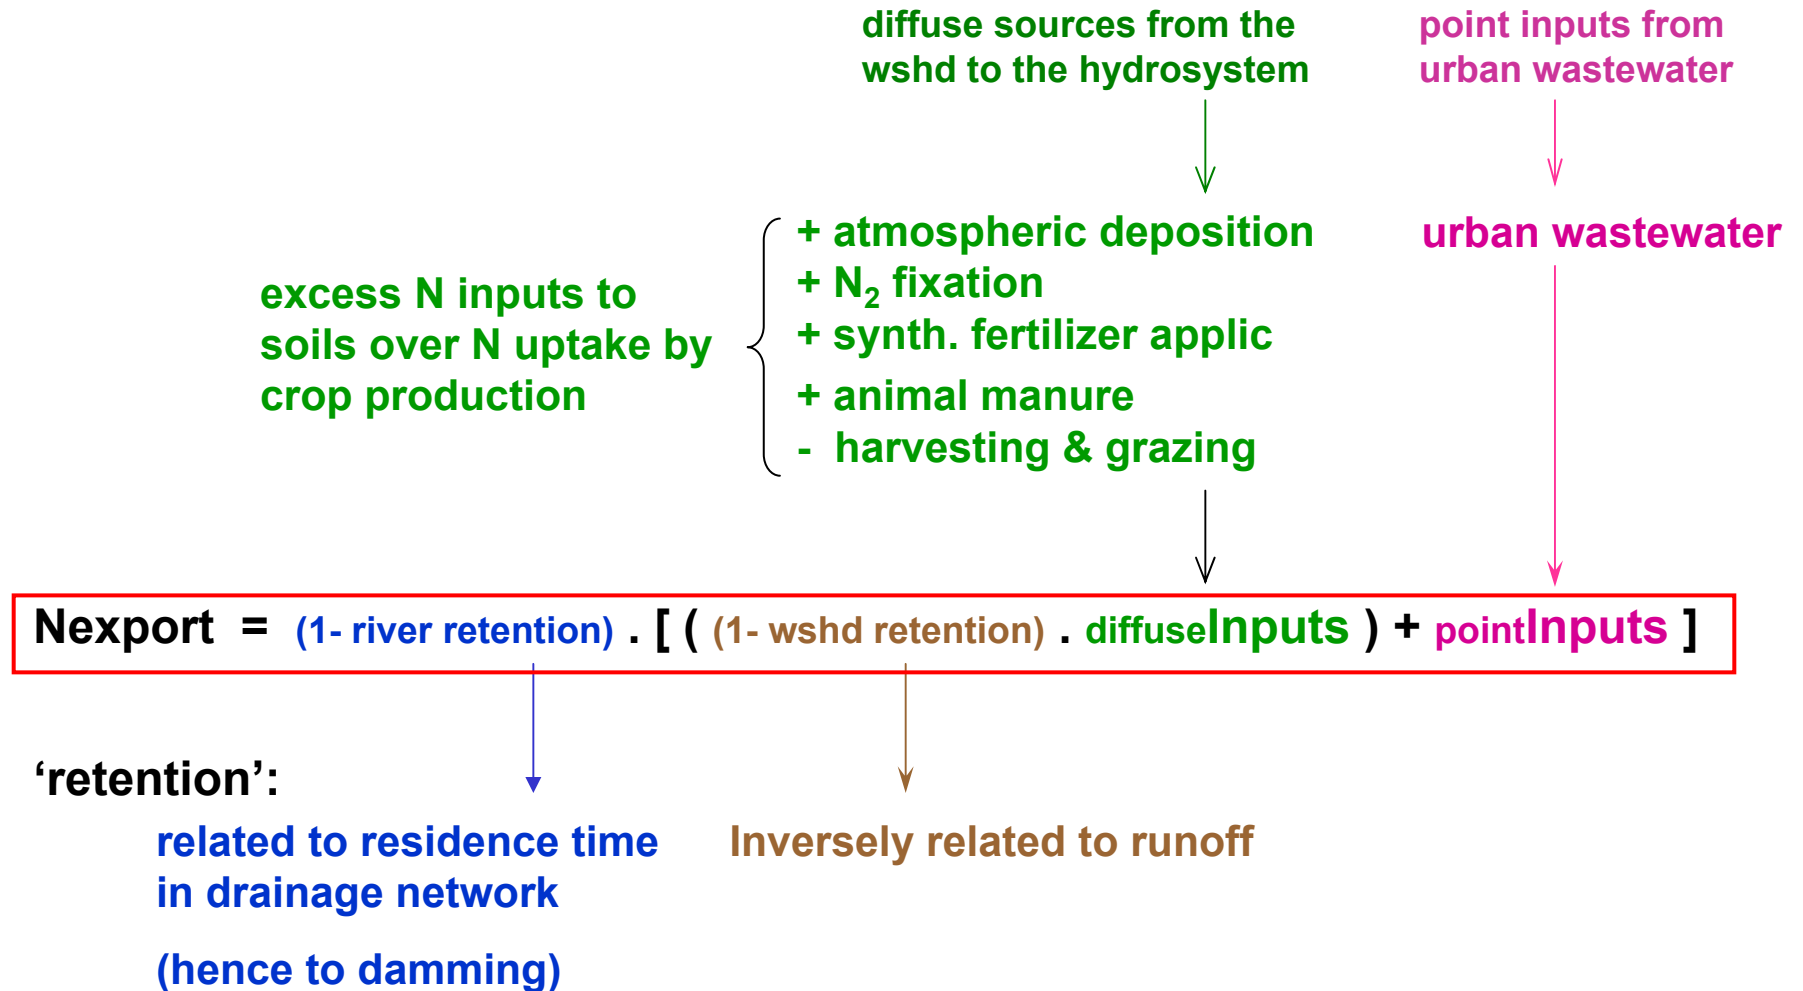

$$\text{Nexport} = (1 - \text{retention}) \cdot \text{NANI} + \text{bckgrd natural export}$$

Riverine delivery only accounts for 10-50% of NANI

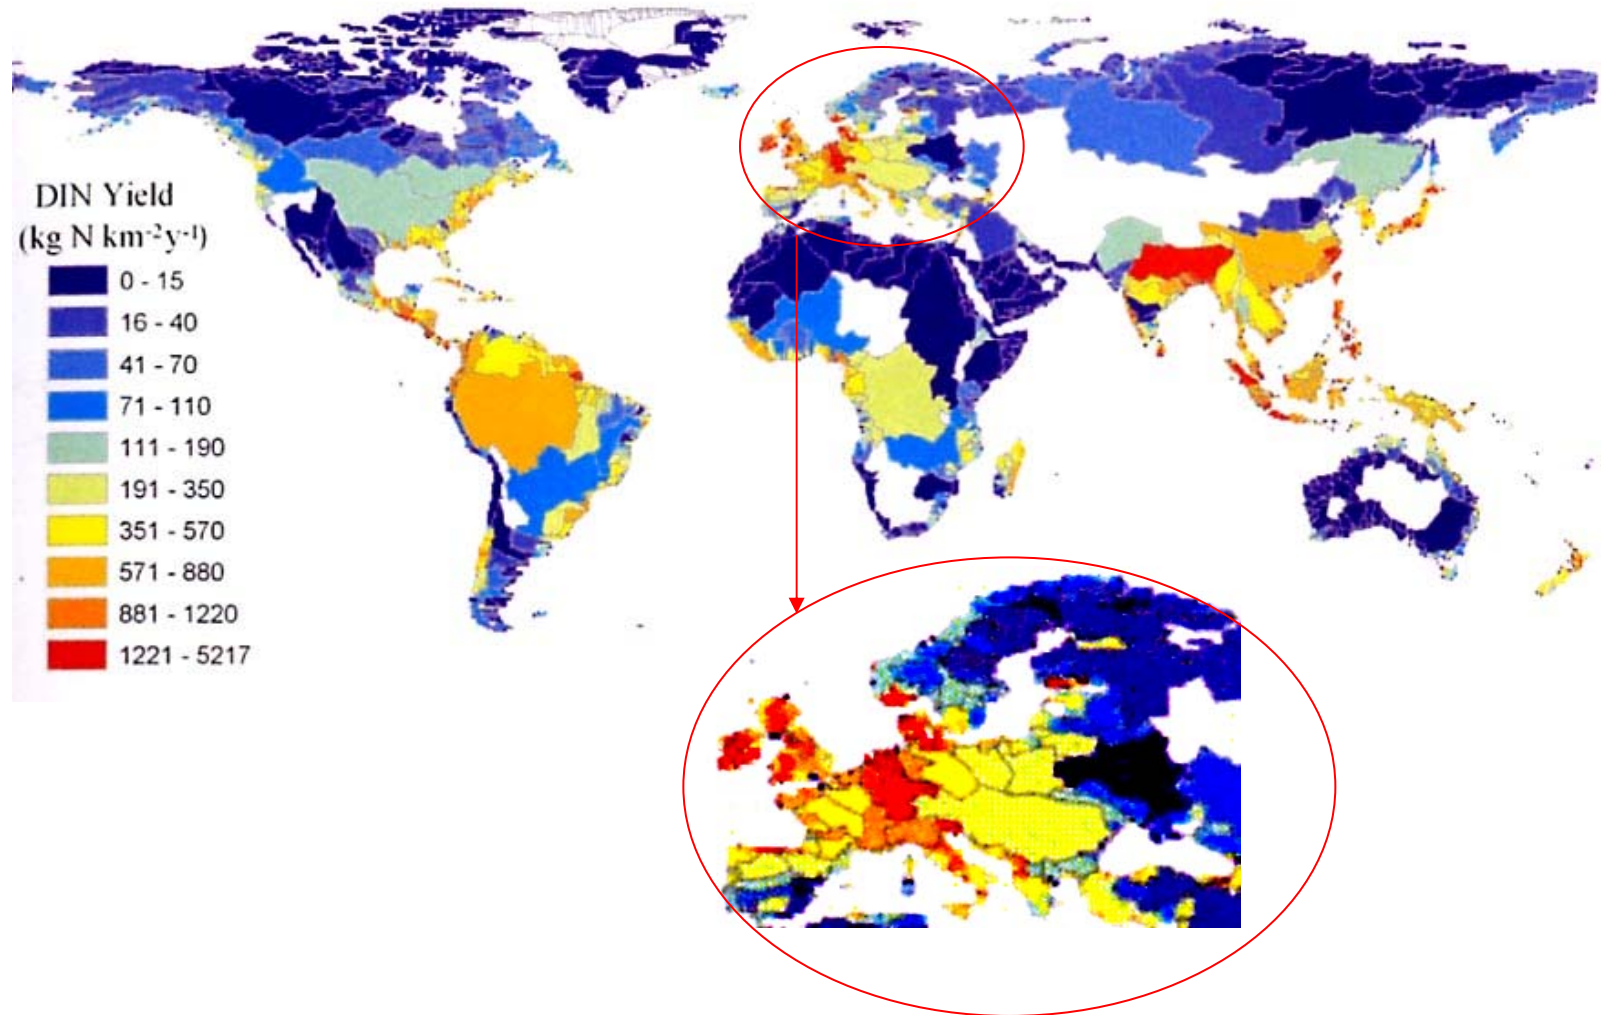

Sparrow, Polflow, GlobNews Models (Smith, 1997; De Wit, 2000; Van Drecht, 2003; Dumont et al. 2005)

Introduce a distinction between

A world wide estimate of river N export

e.g. Dumont et al, 2005

**The possibility of testing future global scenarios
(e.g. Millennium Ecosystem Assessment)**

Questions left unanswered by the input-output regression models:

What is the exact nature of 'retention' ?

What is the fate of the missing N ?

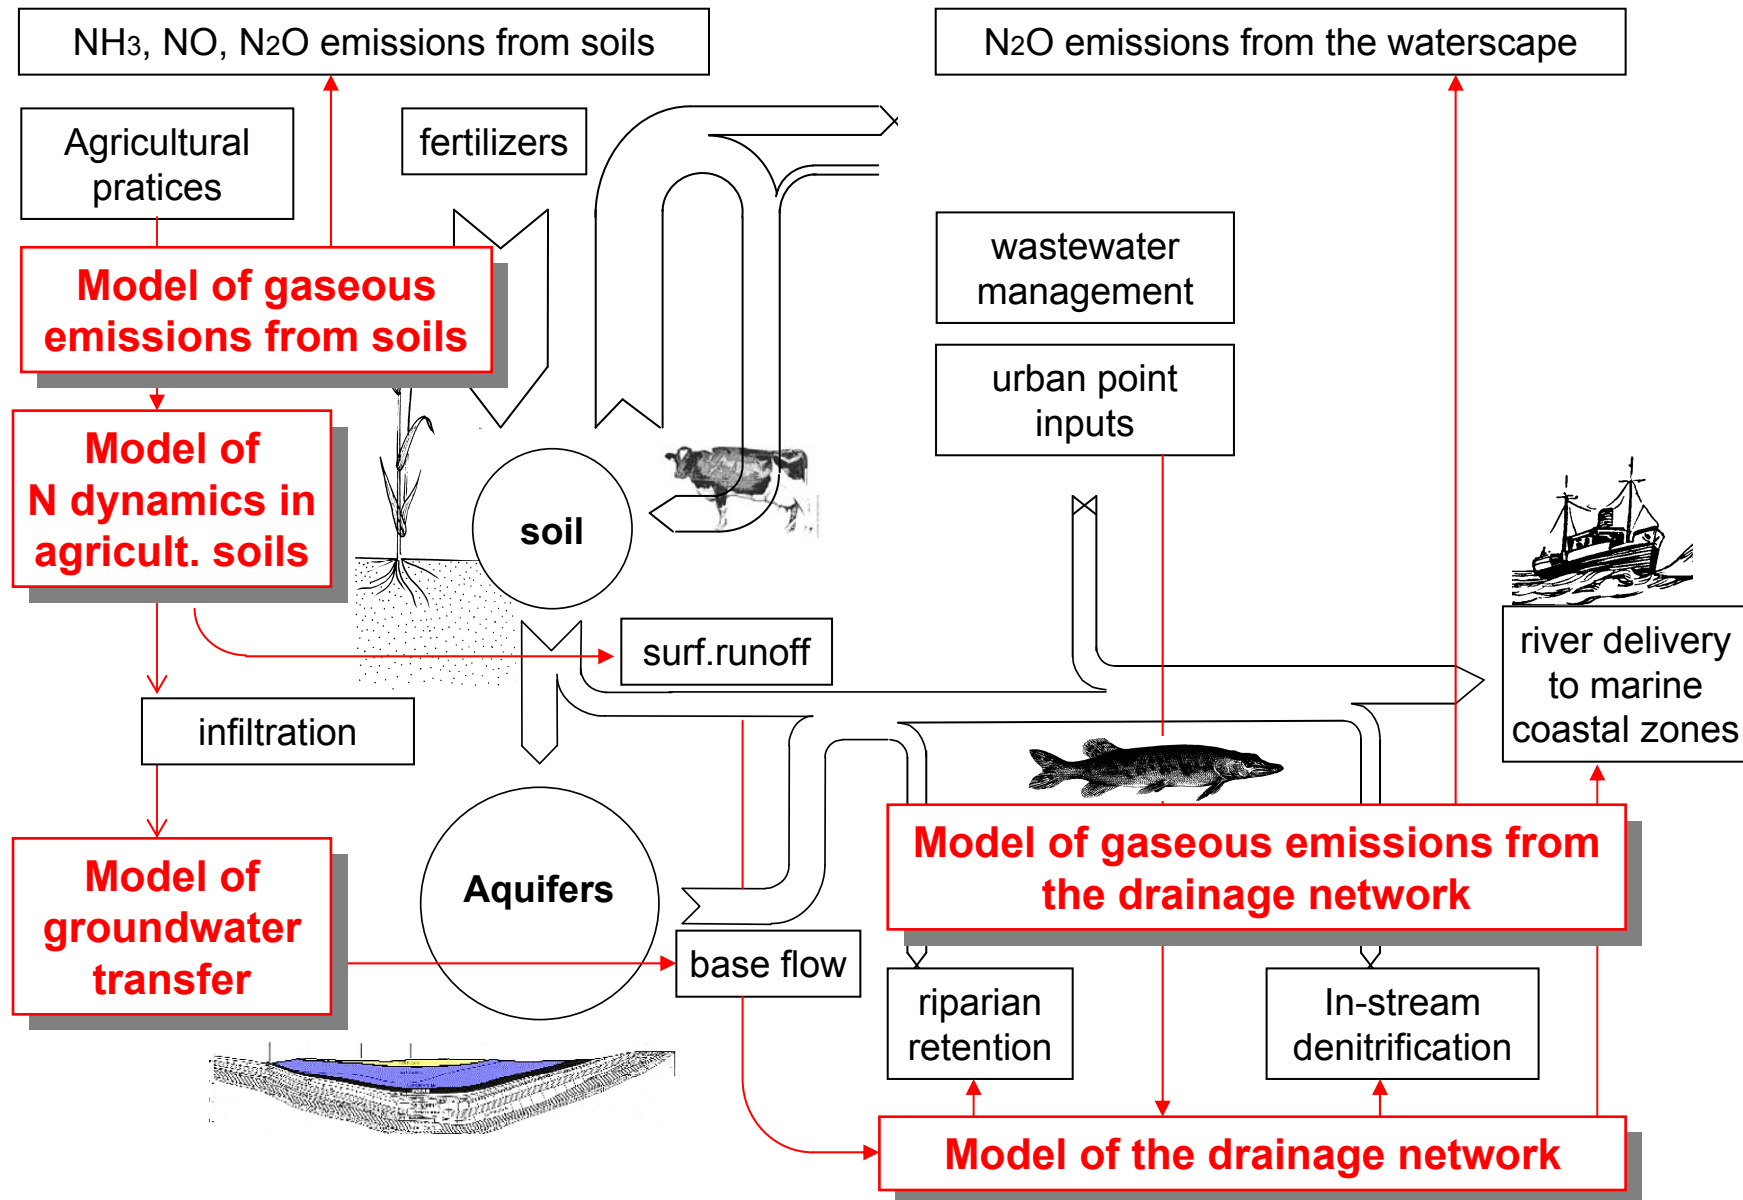

Where are the major retention processes localized in the watershed ?

When are they occurring ?

...

→ **Need for more 'mechanistic' models, with higher level of spatialization, and higher temporal resolution (seasonality)**

Process-based, distributed models of N transfers

2003 (dry hydrological conditions)

in kgN/km²/yr

Testing detailed future scenarios

Agro-environmental measures

Systematic introduction of catch crops in culture rotation could stabilize nitrate contamination of aquifers by 2020

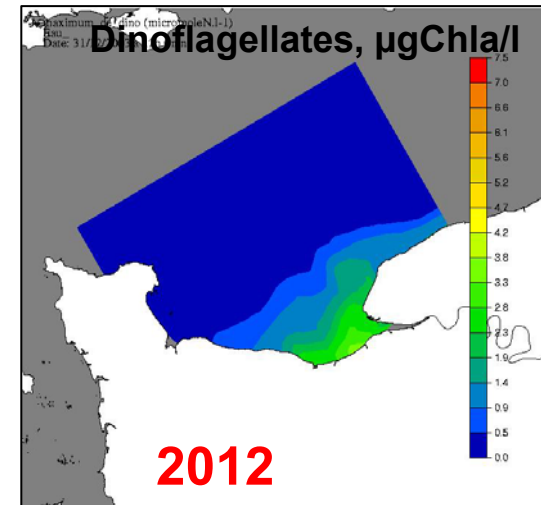

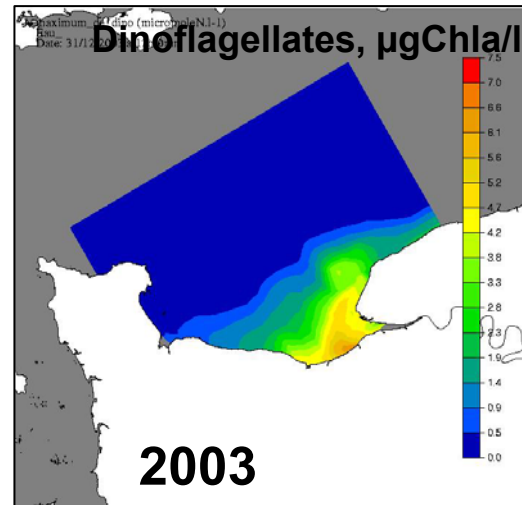

Improvement of wastewater treatment

Introduction of a nitrification step in the treatment line of the biggest Paris wastewater purification plant at Achères considerably reduces ammonium contamination of the river Seine

Although the nitrogen delivery by the Seine river into the sea is predicted to further increase in the next 10 years, the risk of harmful algal blooms will decrease owing to the ongoing reduction of phosphorus loading

Conclusion

Considerable progress has been achieved in modeling the nitrogen cascade at the scale of regional watersheds.

Input-output budgets and regression models are able to quantify the major routes of transfer and retention of anthropogenic Nr.

Chain of process oriented, spatially distributed models are able to reliably predict nitrogen transfer and retention along its cascade from agricultural soils to aquifers, surface water and coastal sea, with a spatial resolution and a degree of details in the description of the process suitable for management scenario analysis.

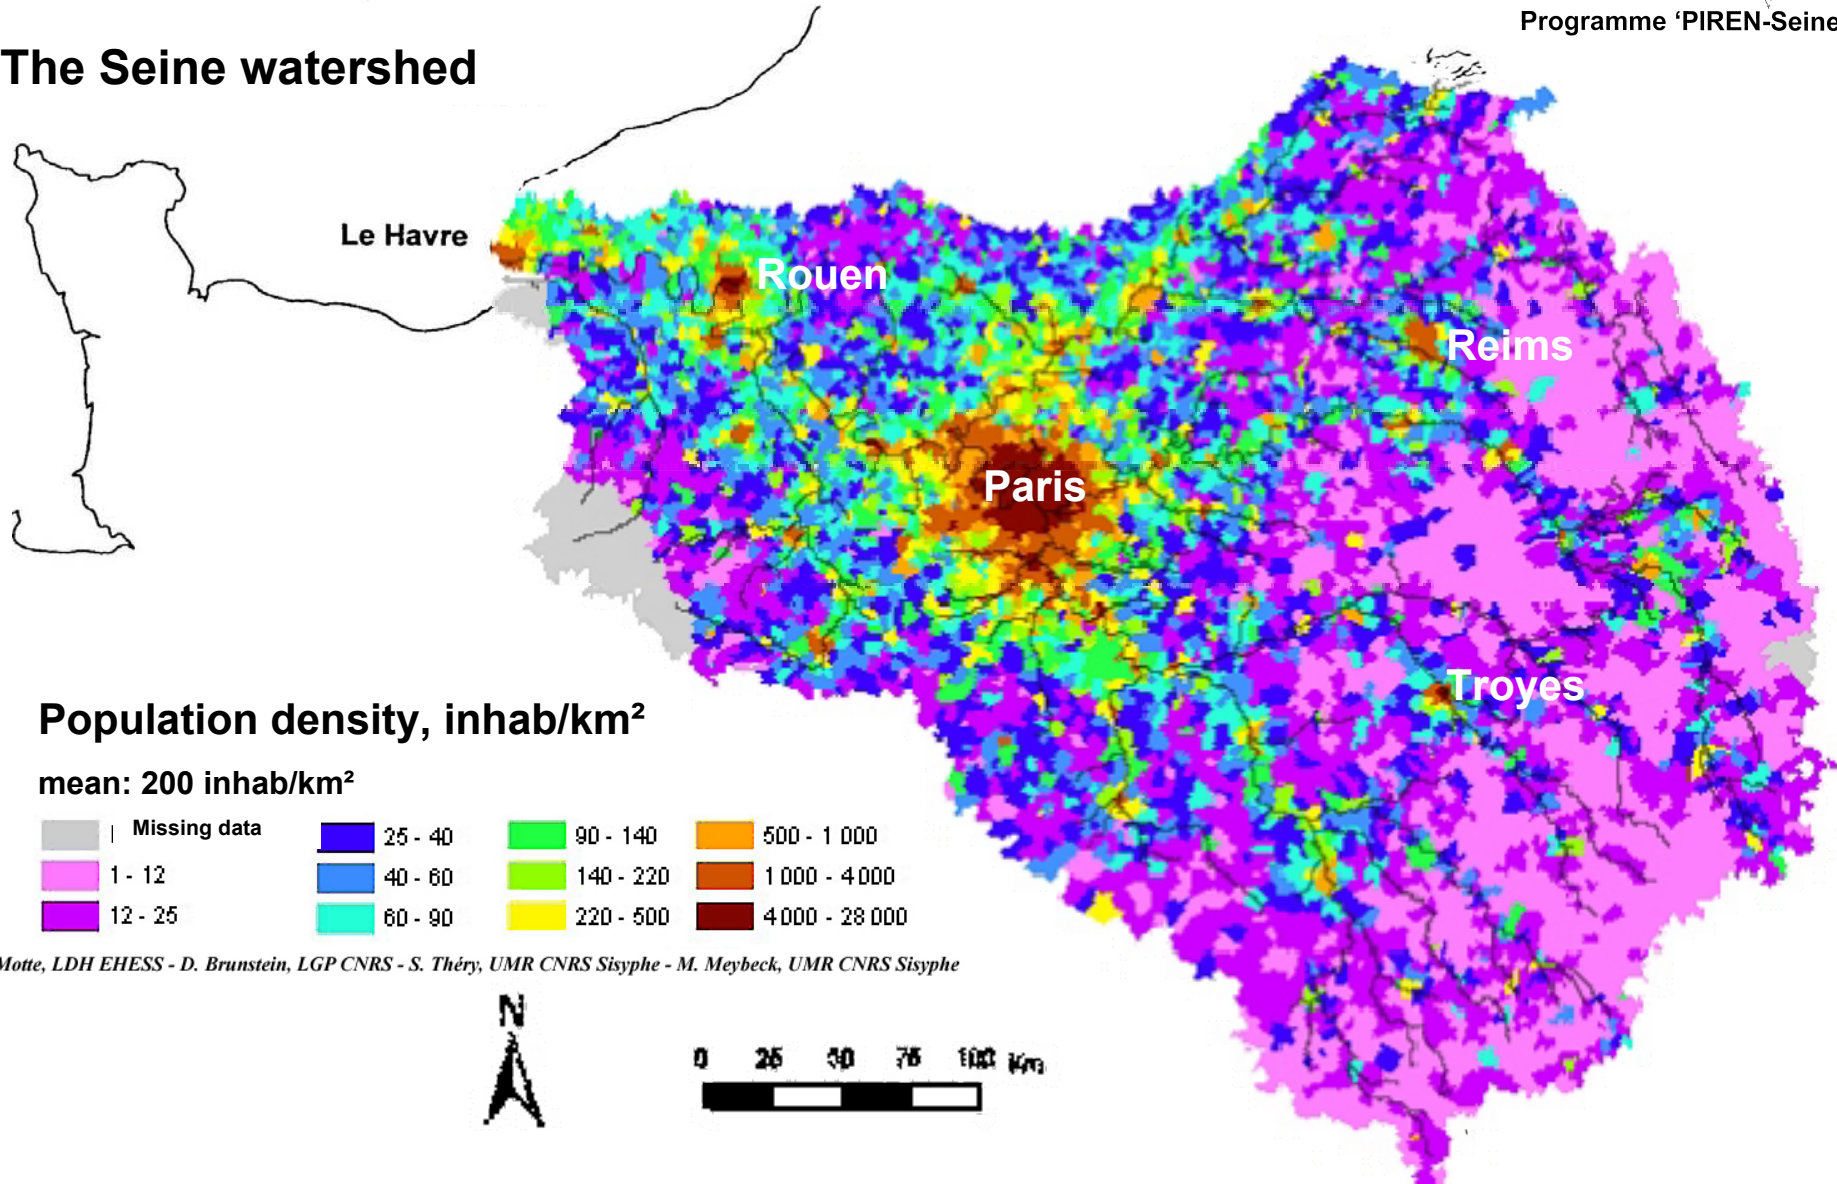

The description of gaseous emission processes, in agricultural soils, wetland and aquatic systems, requires further research efforts.
